**Conflicts of Interest**

PFR is part of the YRE board, however, was not involved in part of the review process.

**Funding Agency**

"SLF and PFR registered in the EMJMD LIVE (Erasmus+ Mundus Joint Master Degree Leading International Vaccinology Education) from 2016 to 2018, co-funded by the EACEA (Education, Audiovisual and Culture Executive Agency, award 2015-2323) of the European commission. SLF has been funded by the University Claude Bernard Lyon-1 with a doctoral contract from the school No205 EDISS."

1  
2 Developing a safe and effective vaccine against severe acute respiratory syndrome corona virus 2 (SARS-  
3 CoV-2) is crucial to ending the COVID-19 pandemic. But even during a global public health crisis,  
4 precautions and careful measures are necessary to ensure that new vaccines are safe for the population  
5 (Hotez et al. 2020).

6 Accelerated vaccine development is being guided and supported by regulatory agencies like the EMA and  
7 the FDA. The WHO has also released the target product profile (TPP) to guide the development of future  
8 vaccines. If the necessary safety and efficacy endpoints are met, the first licensed vaccine candidate should  
9 be available at the beginning of 2021. More than 320 different SARS-CoV-2 vaccine candidates are in  
10 development on a variety of vaccination platforms (Le et al. 2020; LSHTM 2020). Eight of these are  
11 currently being tested for efficacy trials in several thousands of people in high incidence countries.

12 Vaccine design has been hampered by the limited quality and quantity of immunological data on SARS-  
13 CoV-2 (Vabret et al. 2020). Researchers must identify the immune correlates of protection and the  
14 durability of immune responses to create an effective vaccine. They need to determine also the risk-benefit  
15 ratio of vaccination in different populations (e.g., elderly immunocompromised person, recovered cases,  
16 and those as yet unexposed).

17 Researchers working to accelerate SARS-CoV-2 vaccination development have inferred answers to many  
18 of these questions based on data from past coronavirus epidemics (SARS-CoV and MERS-CoV) that  
19 caused severe respiratory syndromes (Ahmed et al. 2020; Vabret et al. 2020). But it is tricky to determine  
20 the portion of the virus that should be included in vaccine formulations to balance efficacy and safety. The  
21 SARS-CoV spike protein, for example, is highly immunogenic, but it may increase antibody-dependent  
22 enhancement that might exacerbate lung disease in people reexposed to the virus (Hotez et al. 2020; Iwasaki  
23 and Yang 2020). Researchers do not know if the primary immune response against SARS-CoV-2 or its  
24 vaccine will exacerbate secondary immune response, so this question must be answered by clinical studies.

25 Efficacy and safety are not the only important criteria. Vaccine candidate production must also be scalable.  
26 Production of authorized vaccines from raw materials can take 6 to 36 months to come to market (Plotkin  
27 et al. 2017), and a delay can drastically increase the number of infected people and the toll that preventive  
28 measures take on a country's economy. Vaccine development and production must thus be expedited.  
29 Therefore, it is important to select the adequate vaccine platform to accelerate vaccine development.

30 Although traditional vaccines (inactivated, live attenuated and subunit vaccines) are now safe and effective  
31 at a low cost per dose, they have several disadvantages during development: it is hard to scale up production  
32 processes, and setting up new manufacturing facilities takes several years to build. Thus, satisfying the  
33 global vaccine demand using traditional vaccine technologies could take two to three years. Newer versatile  
34 vaccination technologies (like vector-based vaccines and nucleic acids vaccines) may be faster and cost-  
35 efficient. For example, nucleic acids vaccination technologies may dramatically decrease development  
36 costs and production, making it easier to scale up during a pandemic (Kis et al. 2018). Validated  
37 manufacturing facilities stand ready to produce nucleic acid vaccines. However, we must be cautious about  
38 these technologies because no nucleic acid vaccines for humans are yet on the market.

Furthermore, there is a multitude of challenges facing routine vaccination. Who will get the vaccine, and how will the vaccination program be implemented? The disease has rapidly spread across the globe, with more than 30 million affected (Dong et al. 2020). The pandemic has resulted in substantial direct and indirect economic losses. Pharmaceutical companies have made enormous investments for vaccine development. With the tremendous demand and the limited supply for the first batch of vaccines, the basic principles of the market economy would be unethical to follow. High-income countries, which have high purchasing capacities, may gain better access to the vaccines, just as the current access to medical supplies and drugs for Covid-19. Similarly, within a country, a disparity in access might occur. The elderly population, who are considered mainly as economic dependents but face a higher risk of dying, would benefit more from the vaccines compared to the income earners who consist mostly of the middle-age group. Ideally, vaccination strategies should be focused first on the more vulnerable populations and those working on the frontlines of the healthcare system to lower the burden of the disease.

In the race for a vaccine, multiple products are needed to meet the enormous global demand. Speeding up the development of new vaccines against SARS-CoV-2 is important, but ensuring safety and efficacy in clinical trials. Future vaccines must ensure the scalability, an adequate price for sustainable investment, and equitable distribution of life-saving vaccines.
